PROPOSAL · LONGER HISTORY

Extract 12–24 months of payment-level data to measure everything over time

What a longer history allows

Narrower intervals.

More TPs per scenario, so colours rest on evidence.

Lag measured. Old months are fully closed, so we can see how precision and days to close settle

What we need to confirm

Scenario versions. Scenarios are retuned,

so history must be split at change dates.

Data retention. How far back case and payment data goes.

Stable definitions. Result, the SQL and the FraudSTATS

with age.

Trends and shifts. Control charts or CUSUM per scenario for precision,

volume and recall.

Back-test. Did red or amber predict later outcomes, and how often did colours change without a real change?

Before and after changes

FraudSTATS fields must not have changed over the period.

Recent months. They stay incomplete however far back we go.

changes. Compare each scenario's precision, recall and alerts around its change date.

Seasonality and drift. Separate seasonal patterns and payment mix from genuine decay.

Ask for a payment-level extract covering at least 12 months, ideally 24: payments screened, confirmed fraud, closure dates and the scenarios that hit each payment, plus the change log for each scenario. With that, every metric in this deck can be calculated by

month. The recent months stay affected by closed-case selection, so they are read with the adjustment from the lag slide.
